

# AUTOMATED IMAGE ANALYSIS

## FOR IDENTIFYING BIOFOULING RISK OF VESSELS

---

**Nathaniel Bloomfield, Bartholomew Woodham, Timothy Carew and Andrew Robinson**

Date: 26/04/2022

# Biosecurity and the challenge of scale

# Biosecurity and the challenge of scale

- Suppose we manage the sea container pathway so that 0.1% of shipping containers carry a biosecurity risk.

# Biosecurity and the challenge of scale

- Suppose we manage the sea container pathway so that 0.1% of shipping containers carry a biosecurity risk.
- As the volume of containers coming into the country increases, we scale up intervention activities to keep this **rate** of leakage constant.

# Biosecurity and the challenge of scale

- Suppose we manage the sea container pathway so that 0.1% of shipping containers carry a biosecurity risk.
- As the volume of containers coming into the country increases, we scale up intervention activities to keep this **rate** of leakage constant.
- This means that...

# Biosecurity and the challenge of scale

- Suppose we manage the sea container pathway so that 0.1% of shipping containers carry a biosecurity risk.
- As the volume of containers coming into the country increases, we scale up intervention activities to keep this **rate** of leakage constant.
- This means that...
  - if 1 million containers are imported, we will have 1000 leakage events.

# Biosecurity and the challenge of scale

- Suppose we manage the sea container pathway so that 0.1% of shipping containers carry a biosecurity risk.
- As the volume of containers coming into the country increases, we scale up intervention activities to keep this **rate** of leakage constant.
- This means that...
  - if 1 million containers are imported, we will have 1000 leakage events.
  - if 2 million containers are imported, there will be 2000 leakage events.

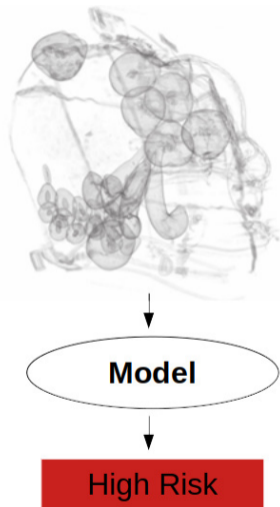

# Biosecurity and the challenge of scale

- Suppose we manage the sea container pathway so that 0.1% of shipping containers carry a biosecurity risk.
- As the volume of containers coming into the country increases, we scale up intervention activities to keep this **rate** of leakage constant.
- This means that...
  - if 1 million containers are imported, we will have 1000 leakage events.
  - if 2 million containers are imported, there will be 2000 leakage events.
- As volumes increase, higher levels of intervention are required maintain current levels of risk.

# Machine Learning can help

- Machine learning aims to develop computational models that can solve time-consuming and repetitive tasks.
- Given an input (passenger information, image, document, video, text, etc.) a machine learning model can support or automate decision making.

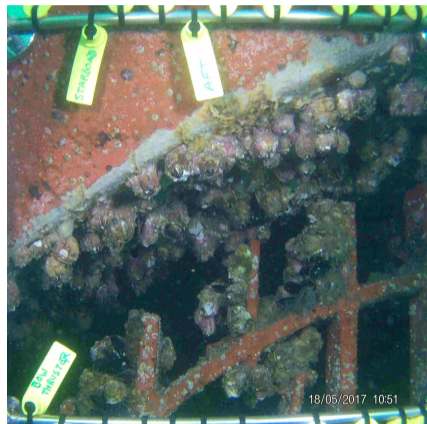

---

<sup>1</sup>Image taken from DAWE's Innovative Biosecurity 3D X-ray Project

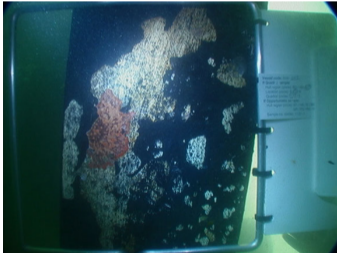

# Machine Learning problems are everywhere in biosecurity

- Does an X-ray image contain a potential biosecurity risk?
- Given what we know about a particular passenger or cargo consignment, are they likely to be carrying biosecurity risks?
- Are the documents provided with a consignment fraudulent?
- **Does the biofouling on this vessel pose a biosecurity risk?**

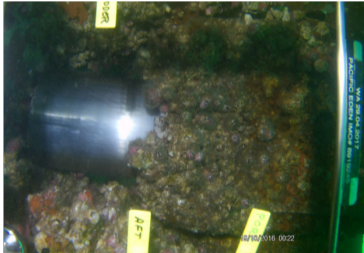

# The Project

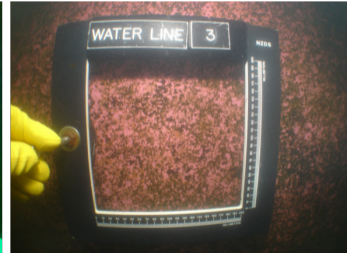

Can we develop a method to assist/automate the assessment of images and footage for biofouling?

Level of fouling X?

Level of fouling Y?

Level of fouling Z?

# The Project: Use Cases

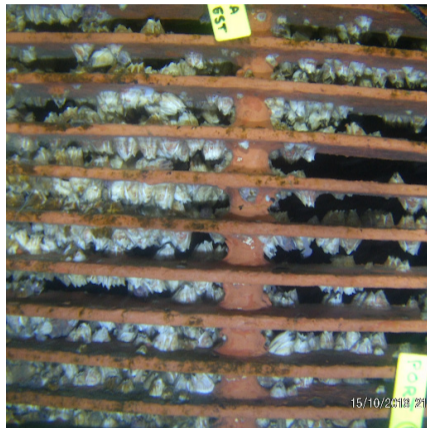

# Building a machine learning model

1. What is the decision that I need the computer to make?
2. What data could be used to train the model?
3. Does my model perform well enough?

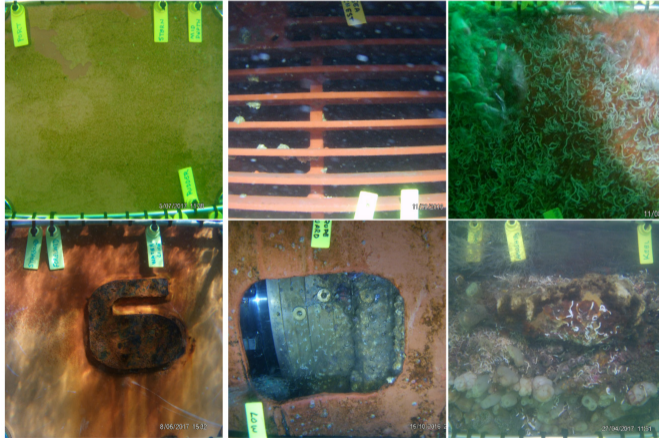

# 1. What is the decision that I need the computer to make?

- Biosecurity regulators care about the overall state of the vessel
  - Overall, how severe is fouling on the vessel?
  - Are particular areas badly fouled (e.g. sea chests)
  - Are there species of concern?
- These high level questions are challenging!

# Defining a labelling scheme

An **easier** question: In an image, what is the degree of fouling present?

(a) SLoF 0

(b) SLoF 1

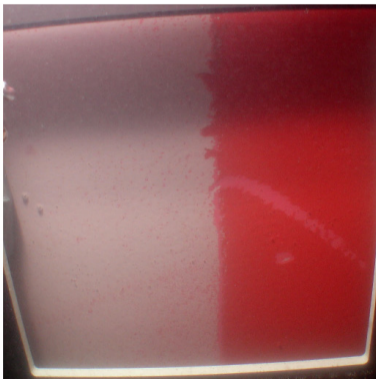

(c) SLoF 2

# The data-labelling process

[Click here to show examples](#)

## Select the most appropriate box for the image

Image can be zoomed with mousewheel and panned by clicking and dragging.

What fouling description best reflects this image? (hotkeys are 1, 2 and 3)

No fouling organisms, but biofilm or slime **MAY** be present.

Fouling organisms (e.g. barnacles, mussels, seaweed, tubeworms, etc.) are visible but patchy (1-15% of surface covered).

A large number of fouling organisms are present (16-100% of surface covered).

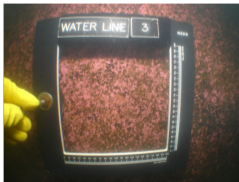

Submit (hotkey enter)

## 2. What data could be used to train the model?

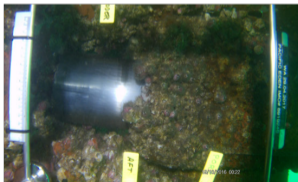

- Obtained over 10,000 images from NZ MPI, the Australian DAWE and California's SLC.
- Around 300 vessels represented including commercial, recreational and barge vessels.
- Dataset was highly imbalanced! Around 70% of images were clean, 20% lightly fouled, and 10% heavily fouled.

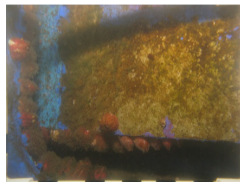

NZ Recreational

NZ Commercial

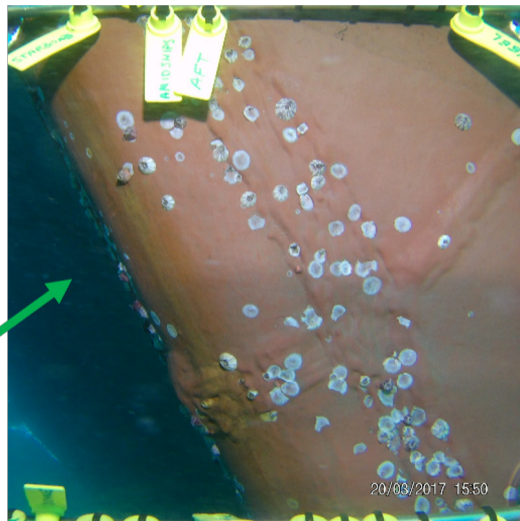

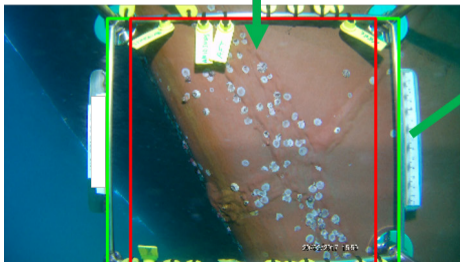

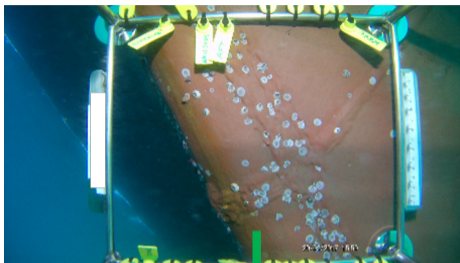

DAWE

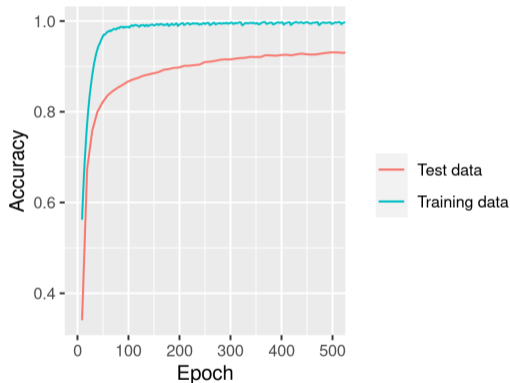

California SLC

# Processing the data

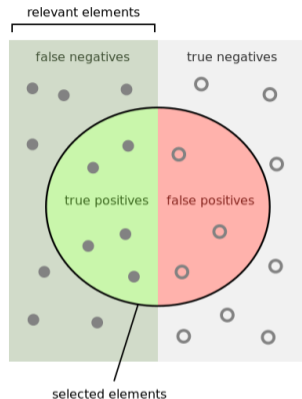

# Training the models

1. Split the data into a **training** and a **test** set.
2. Optimise the model on the **training** set.
3. Evaluate model performance on the with-held **test** data.

### 3. Does the model perform well enough?

- **Accuracy** — proportion of images correctly identified.
- **Recall** — proportion of images with a biosecurity risk that we correctly identify (true positives versus false negatives)
- **Precision** — proportion of flagged images that actually have a biosecurity risk (true positives versus false positives)
- As model output is a raw number (e.g. 0.45) we need to define thresholds to obtain predicted classes before we can calculate precision and recall!

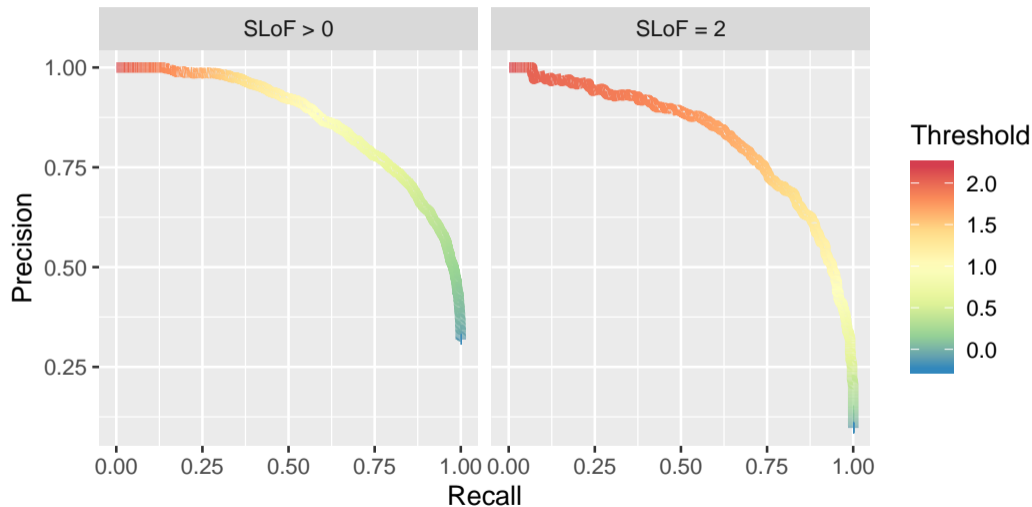

$$\text{Accuracy} = 12/22$$

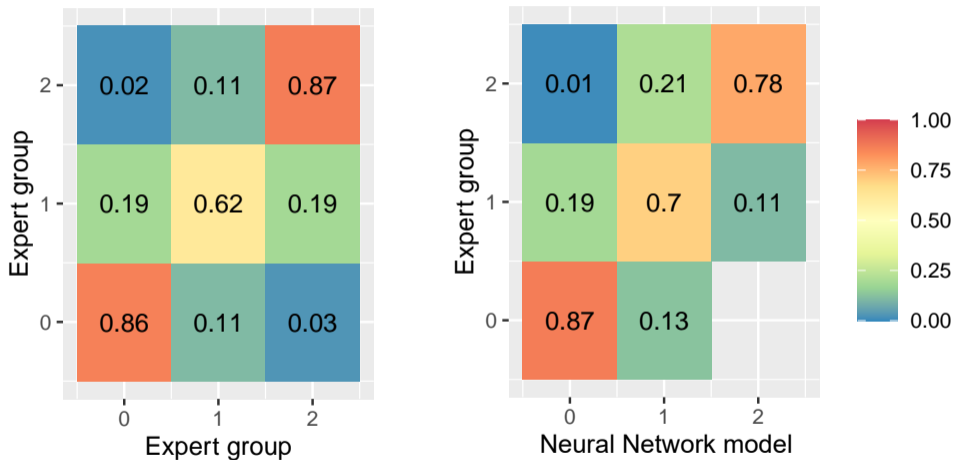

$$\text{Precision} = 5/8$$

$$\text{Recall} = 5/12$$

# Model criteria: precision-recall curve

# Comparing the neural network model to expert agreement

# Apply the model to real-world data

SLoF 1

SLoF 0

- A multi-year CEBRA project is currently ongoing to further develop and support the operationalization this work. The key objectives include:
  - Expanding the image dataset to include examples from commercial vessel surveys
  - Develop cost-effective strategies for labelling and incorporating new data
  - Extend the approach to video data
  - Integrating the neural network models with a prototype user interface

# Acknowledgments

- Thanks to Ramboll New Zealand for providing experts to classify our test set of images and the Mechanical Turk workers that contributed to the project.
- Thanks to Daniel Kluza from the New Zealand Ministry of Primary Industries for providing their biofouling dataset.
- Thanks to Chris Scianni from the Californian State Lands Commission for providing their biofouling dataset.
- This research was undertaken using the LIEF HPC-GPGPU Facility hosted at the University of Melbourne. This Facility was established with the assistance of LIEF Grant LE170100200.
